Operating Systems

28. Locks

Locks: The Basic Idea

- Ensure that any **critical section** executes as if it were a single atomic instruction.

    - An example: the canonical update of a shared variable

    ```
    balance = balance + 1;
    ```

    - Add some code around the critical section

    ```
    1    lock_t mutex; // some globally-allocated lock 'mutex'
    2    …
    3    lock(&mutex);
    4    balance = balance + 1;
    5    unlock(&mutex);
    ```

Locks: The Basic Idea

- Lock variable holds <u>the state of </u>the lock.

  - **available** (or **unlocked** or **free**)

    - No thread holds the lock.

  - **acquired** (or **locked** or **held**)

    - Exactly one thread holds the lock and presumably is in a critical section.

The semantics of the lock()

- `lock()`

  - **Try to** acquire the lock.

  - If <u>no other thread holds</u> the lock, the thread will **acquire** the lock.

  - **Enter** the *critical section*.

    - This thread is said to be <u>the owner of</u> the lock.

  - Other threads are *prevented from* entering the critical section while the first thread that holds the lock is in there.

Pthread Locks – mutex

□ The name that the POSIX library uses for a <u>lock</u>.

◆ Used to provide mutual exclusion between threads.

```
1   pthread_mutex_t lock = PTHREAD_MUTEX_INITIALIZER;
2
3   Pthread_mutex_lock(&lock); // wrapper for pthread_mutex_lock()
4   balance = balance + 1;
5   Pthread_mutex_unlock(&lock);
```

◆ We may be using *different locks* to protect *different variables* → Increase concurrency (a more **fine-grained** approach).

Building A Lock

- <u>Efficient locks</u> provided mutual exclusion at low cost.

- Building a lock need some help from the **hardware** and the **OS**.

Evaluating locks – Basic criteria

- **Mutual exclusion**
  - ◆ Does the lock work, preventing multiple threads from entering *a critical section*?

- **Fairness**
  - ◆ Does each thread contending for the lock get a fair shot at acquiring it once it is free? (Starvation)

- **Performance**
  - ◆ The time overheads added by using the lock

Controlling Interrupts

- **Disable Interrupts** for critical sections

  - One of the earliest solutions used to provide mutual exclusion

  - Invented for <u>single-processor</u> systems.

  ```
  1   void lock() {
  2       DisableInterrupts();
  3   }
  4   void unlock() {
  5       EnableInterrupts();
  6   }
  ```

  - Problem:

    - Require too much *trust* in applications

      - Greedy (or malicious) program could monopolize the processor.

    - Do not work on multiprocessors.

    - Code that masks or unmasks interrupts be executed *slowly* by modern CPUs.

Why hardware support needed?

- **First attempt**: Using a *flag* denoting whether the lock is held or not.
  - The code below has problems.

```c
1    typedef struct __lock_t { int flag; } lock_t;
2
3    void init(lock_t *mutex) {
4        // 0 → lock is available, 1 → held
5        mutex->flag = 0;
6    }
7
8    void lock(lock_t *mutex) {
9        while (mutex->flag == 1)  // TEST the flag
10                   ;  // spin-wait (do nothing)
11       mutex->flag = 1;  // now SET it !
12   }
13
14   void unlock(lock_t *mutex) {
15       mutex->flag = 0;
16   }
```

Why hardware support needed? (Cont.)

- **Problem 1**: No Mutual Exclusion (assume `flag=0` to begin)

Thread1	Thread2

`call lock()`
`while (flag == 1)`
interrupt: switch to Thread 2	

	`call lock()`
	`while (flag == 1)`
	`flag = 1;`
	interrupt: switch to Thread 1

`flag = 1;` // set flag to 1 (too!)	

- **Problem 2**: <u>Spin-waiting</u> wastes time waiting for another thread.

- So, we need an atomic instruction supported by Hardware!

  - *test-and-set* instruction, also known as *atomic exchange*

Test And Set (Atomic Exchange)

- An instruction to support the creation of simple locks

```
1    int TestAndSet(int *ptr, int new) {
2         int old = *ptr;   // fetch old value at ptr
3         *ptr = new;        // store 'new' into ptr
4         return old;        // return the old value
5    }
```

- **return**(testing) old value pointed to by the `ptr`.

- *Simultaneously* **update**(setting) said value to `new`.

- This sequence of operations is performed atomically.

A Simple Spin Lock using test-and-set

```c
1    typedef struct __lock_t {
2        int flag;
3    } lock_t;
4
5    void init(lock_t *lock) {
6        // 0 indicates that lock is available,
7        // 1 that it is held
8        lock->flag = 0;
9    }
10
11   void lock(lock_t *lock) {
12       while (TestAndSet(&lock->flag, 1) == 1)
13               ;            // spin-wait
14   }
15
16   void unlock(lock_t *lock) {
17       lock->flag = 0;
18   }
```

◆ **Note**: To work correctly on *a single processor*, it requires <u>a preemptive scheduler</u>.

Evaluating Spin Locks

- **Correctness**: yes

  - The spin lock only allows a single thread to entry the critical section.

- **Fairness**: no

  - Spin locks <u>don't provide any fairness</u> guarantees.

  - Indeed, a thread spinning may spin *forever*.

- **Performance**:

  - In the single CPU, performance overheads can be quire *painful*.

  - If the number of threads roughly equals the number of CPUs, spin locks work *reasonably well*.

Compare-And-Swap (SPARC)

□ Test whether the value at the address(`ptr`) is equal to `expected`.

 ◆ *If so*, update the memory location pointed to by `ptr` with the `new` value.

 ◆ *In either case*, return the actual value at that memory location.

```
1    int CompareAndSwap(int *ptr, int expected, int new) {
2        int actual = *ptr;
3        if (actual == expected)
4                *ptr = new;
5        return actual;
6    }
```
Compare-and-Swap hardware atomic instruction (C-style)

```
1    void lock(lock_t *lock) {
2        while (CompareAndSwap(&lock->flag, 0, 1) == 1)
3                ; // spin
4    }
```
Spin lock with compare-and-swap

Compare-And-Exchange (x86)

- C-callable x86-version of compare-and-swap

```
1    char CompareAndSwap(int *ptr, int old, int new) {
2         unsigned char ret;
3
4         // Note that sete sets a 'byte' not the word
5         __asm__ __volatile__ (
6                   " lock\n"
7                   " cmpxchgl %2,%1\n"
8                   " sete %0\n"
9                   : "=q" (ret), "=m" (*ptr)
10                  : "r" (new), "m" (*ptr), "a" (old)
11                  : "memory");
12        return ret;
13   }
```

Load-Linked and Store-Conditional (MIPS)

```
1    int LoadLinked(int *ptr) {
2        return *ptr;
3    }
4
5    int StoreConditional(int *ptr, int value) {
6        if (no one has updated *ptr since the LoadLinked to this address) {
7            *ptr = value;
8            return 1; // success!
9        } else {
10           return 0; // failed to update
11       }
12   }
```

Load-linked And Store-conditional

- The store-conditional *only succeeds* if no intermittent store to the address has taken place.

  - **success**: return 1 and <u>update</u> the value at `ptr` to `value`.

  - **fail**: the value at `ptr` is <u>not updates</u> and 0 is returned.

Load-Linked and Store-Conditional (Cont.)

```
1    void lock(lock_t *lock) {
2        while (1) {
3                while (LoadLinked(&lock->flag) == 1)
4                        ; // spin until it's zero
5                if (StoreConditional(&lock->flag, 1) == 1)
6                        return; // if set-it-to-1 was a success: all done
7                                otherwise: try it all over again
8        }
9    }
10
11   void unlock(lock_t *lock) {
12       lock->flag = 0;
13   }
```

Using LL/SC To Build A Lock

```
1    void lock(lock_t *lock) {
2        while (LoadLinked(&lock->flag)||!StoreConditional(&lock->flag, 1))
3                ; // spin
4    }
```

A more concise form of the `lock()` using LL/SC

Fetch-And-Add

- Atomically increment a value while returning the old value at a particular address.

```
1    int FetchAndAdd(int *ptr) {
2        int old = *ptr;
3        *ptr = old + 1;
4        return old;
5    }
```

Fetch-And-Add Hardware atomic instruction (C-style)

Ticket Lock

- **Ticket lock** can be built with <u>fetch-and add</u>.

  - ◆ Ensure progress for all threads. → fairness

```
1    typedef struct __lock_t {
2        int ticket;
3        int turn;
4    } lock_t;
5
6    void lock_init(lock_t *lock) {
7        lock->ticket = 0;
8        lock->turn = 0;
9    }
10
11   void lock(lock_t *lock) {
12       int myturn = FetchAndAdd(&lock->ticket);
13       while (lock->turn != myturn)
14                   ; // spin
15   }
16   void unlock(lock_t *lock) {
17       FetchAndAdd(&lock->turn);
18   }
```

So Much Spinning

- Hardware-based spin locks are simple and they work.

- In some cases, these solutions can be quite inefficient.

  - Any time a thread gets caught *spinning*, it **wastes an entire time slice** doing nothing but checking a value.

> **How To Avoid *Spinning*?**
> **We'll need OS Support too!**

A Simple Approach: Just Yield

□ When you are going to spin, give up the CPU to another thread.

- ◆ OS system call moves the caller from the *running state* to the *ready state*.

- ◆ The cost of a **context switch** can be substantial and the **starvation** problem still exists.

```
1    void init() {
2         flag = 0;
3    }
4
5    void lock() {
6         while (TestAndSet(&flag, 1) == 1)
7             yield(); // give up the CPU
8    }
9
10   void unlock() {
11        flag = 0;
12   }
```

Lock with Test-and-set and Yield

Using Queues: Sleeping Instead of Spinning

▫ **Queue** to keep track of which threads are <u>waiting</u> to enter the lock.

▫ `park()`

  ◆ Put a calling thread to sleep

▫ `unpark(threadID)`

  ◆ Wake a particular thread as designated by `threadID`.

```
typedef struct __lock_t {
    int flag;        // lock is acquired or not
    int guard;       // to protect the queue
    queue_t *q;
} lock_t;
```

Using Queues: Sleeping Instead of Spinning

```c
1    typedef struct __lock_t { int flag; int guard; queue_t *q; } lock_t;
2
3    void lock_init(lock_t *m) {
4        m->flag = 0;
5        m->guard = 0;
6        queue_init(m->q);
7    }
8
9    void lock(lock_t *m) {
10       while (TestAndSet(&m->guard, 1) == 1)
11           ; // acquire guard lock by spinning
12       if (m->flag == 0) {
13           m->flag = 1; // lock is acquired
14           m->guard = 0;
15       } else {
16           queue_add(m->q, gettid());
17           m->guard = 0;
18           park();
19       }
20   }
21   …
```

Lock With Queues, Test-and-set, Yield, And Wakeup

Using Queues: Sleeping Instead of Spinning

```
22   void unlock(lock_t *m) {
23       while (TestAndSet(&m->guard, 1) == 1)
24           ; // acquire guard lock by spinning
25       if (queue_empty(m->q))
26           m->flag = 0; // let go of lock; no one wants it
27       else
28           unpark(queue_remove(m->q)); // hold lock (for next thread!)
29       m->guard = 0;
30   }
```

Lock With Queues, Test-and-set, Yield, And Wakeup (Cont.)

Wakeup/waiting race

- In case of releasing the lock (*thread A*) just before the call to `park()` (*thread B*) → Thread B would sleep forever (potentially).

- **Solaris** solves this problem by adding a third system call: `setpark()`.
  - By calling this routine, a thread can indicate it *is about to* `park`.
  - If it happens to be interrupted and another thread calls `unpark` before `park` is actually called, the subsequent `park` returns immediately instead of sleeping.

```
1              queue_add(m->q, gettid());
2              setpark(); // new code
3              m->guard = 0;
4              park();
```

Code modification inside of `lock()`

Futex

- Linux provides a futex (is similar to Solaris's `park` and `unpark`).

  - `futex_wait(address, expected)`

    - Put the calling thread to sleep

    - If the value at `address` is not equal to `expected`, the call returns immediately.

  - `futex_wake(address)`

    - Wake one thread that is waiting on the queue.

Futex (Cont.)

- Snippet from `lowlevellock.h` in the **nptl** library

  - ◆ The high bit of the integer `v`: track whether the lock is held or not

  - ◆ All the other bits : the number of waiters

```
1    void mutex_lock(int *mutex) {
2        int v;
3        /* Bit 31 was clear, we got the mutex (this is the fastpath) */
4        if (atomic_bit_test_set(mutex, 31) == 0)
5                return;
6        atomic_increment(mutex);
7        while (1) {
8                if (atomic_bit_test_set(mutex, 31) == 0) {
9                        atomic_decrement(mutex);
10                        return;
11                }
12                /* We have to wait now. First make sure the futex value
13                    we are monitoring is truly negative (i.e. locked). */
14                v = *mutex;
15                …
```

Linux-based Futex Locks

```
16              if (v >= 0)
17                      continue;
18          futex_wait(mutex, v);
19      }
20  }
21
22  void mutex_unlock(int *mutex) {
23      /* Adding 0x80000000 to the counter results in 0 if and only if
24          there are not other interested threads */
25      if (atomic_add_zero(mutex, 0x80000000))
26              return;
27      /* There are other threads waiting for this mutex,
28          wake one of them up */
29      futex_wake(mutex);
30  }
```

Linux-based Futex Locks (Cont.)

Two-Phase Locks

□ A two-phase lock realizes that spinning can be useful if the lock *is about to* be released.

- **First phase**
  - The lock spins for a while, *hoping that* it can acquire the lock.
  - If the lock is not acquired during the first spin phase, a second phase is entered,

- **Second phase**
  - The caller is put to sleep.
  - The caller is only woken up when the lock becomes free later.

Summary

- Hardware support

  - Test-and-set

  - Compare-and-swap (SPARC, x86)

  - Load-linked and store conditional (ll/sc, MIPS)

- OS support

  - park()/unpark()/setpark()

  - futex

  - Two-phase locks
